Overview of Recommendation Engine

User Interest is implicitly reflected in:

- Interaction history
- Demographics ...
- Contexts

Items can be:

Products, News, Movies,
Videos, Friends ...

Key challenge: user-item semantic gap

- user and item are two **different types of entities** and are represented by different features.

Problem Formulation

- **Input:** historical user-item interactions or additional side information (e.g., user profile, item profile)
- **Output:** given a target Item (e.g., movie, song, product), how likely a user would interact with it (e.g., click, view, or purchase)

User Profile:

- User ID
- Rating history
- Age, Gender
- Clicks
- Income level

.....

Item Profile:

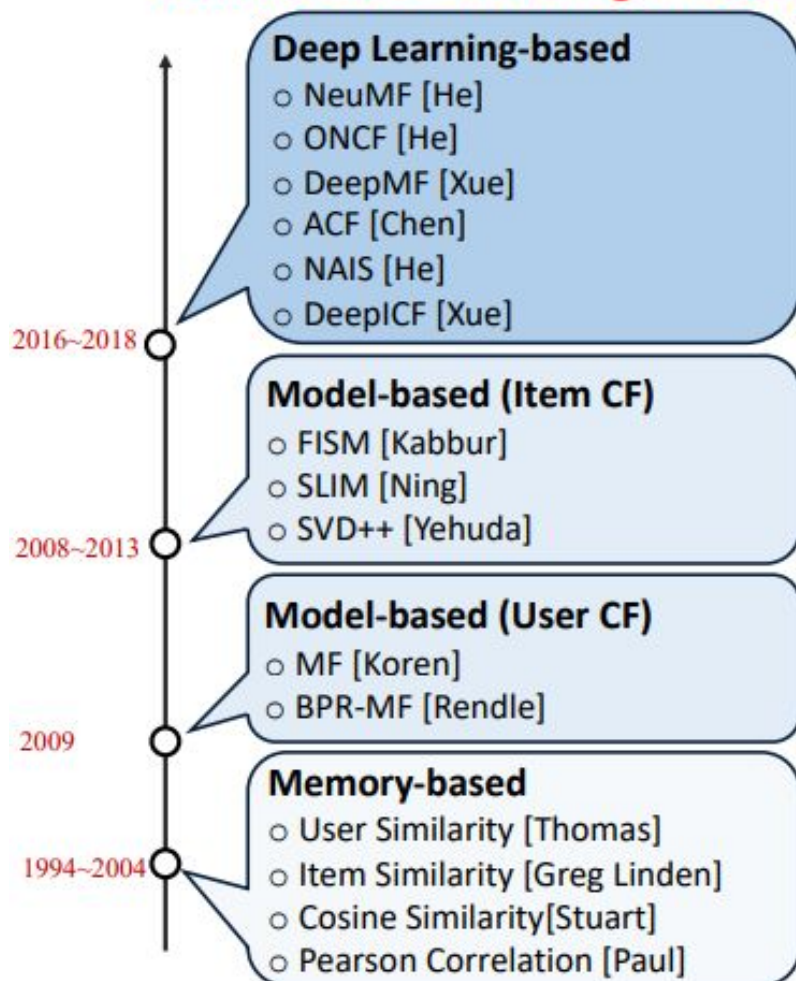

- Item ID
- Description
- Image
- Category
- Price

.....

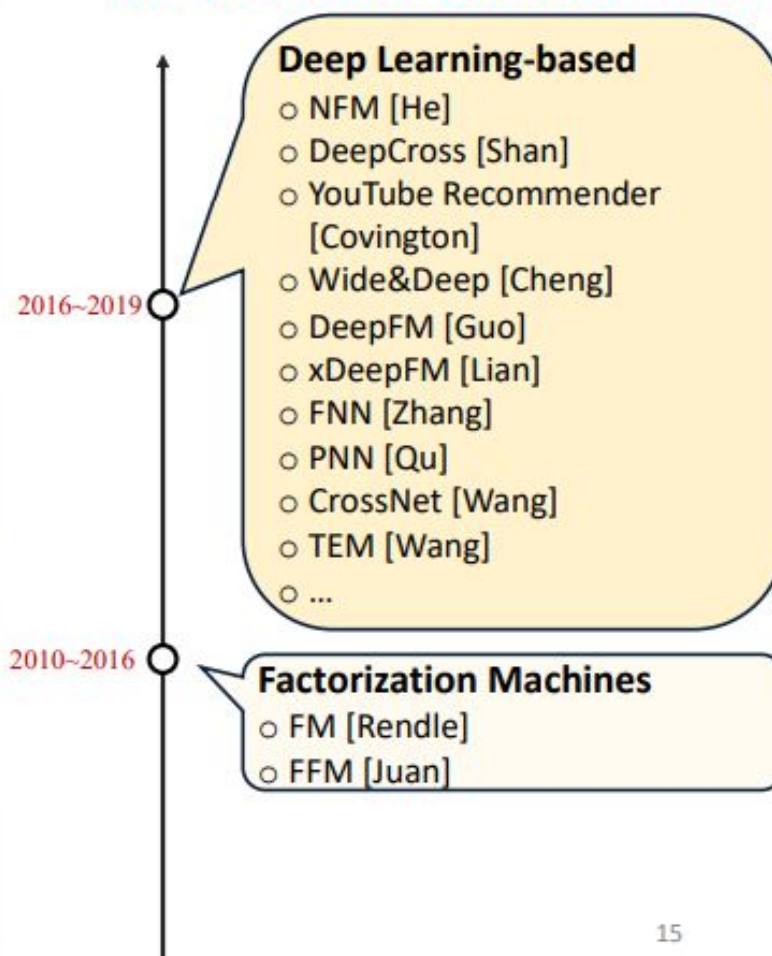

There may be **no overlap** between user features and item features.

Research on Prevalent RecSys

Collaborative Filtering Models

Generic Feature-based Models

Collaborative Filtering (CF)

- **CF** is the most well-known technique for recommendation.
 - “CF makes predictions (**filtering**) about a user’s interest by collecting preferences information from many users (**collaborating**)” ---Wikipedia
- Collaborative Signals → Behavior Similarity of Users
 - Similar users would have similar preference on items.

$(u_1 \text{ (blue circle)} \quad i_1 \text{ (white circle)}) \quad 5$

$(u_2 \text{ (blue circle)} \quad i_1 \text{ (white circle)}) \quad 3$

$(u_2 \text{ (blue circle)} \quad i_2 \text{ (white circle)}) \quad 4$

$(u_3 \text{ (blue circle)} \quad i_2 \text{ (white circle)}) \quad 1$

$(u_3 \text{ (blue circle)} \quad i_3 \text{ (white circle)}) \quad 2$

$(u_3 \text{ (blue circle)} \quad i_4 \text{ (white circle)}) \quad 4$

... ..

		item				
		1	2	3	4	
user	1	5	?	?	?	...
	2	3	4	?	?	...
	3	?	1	2	4	...
	

Interaction Matrix

1. Memory-based CF:

Predict by **memorizing** similar users' (or items') ratings

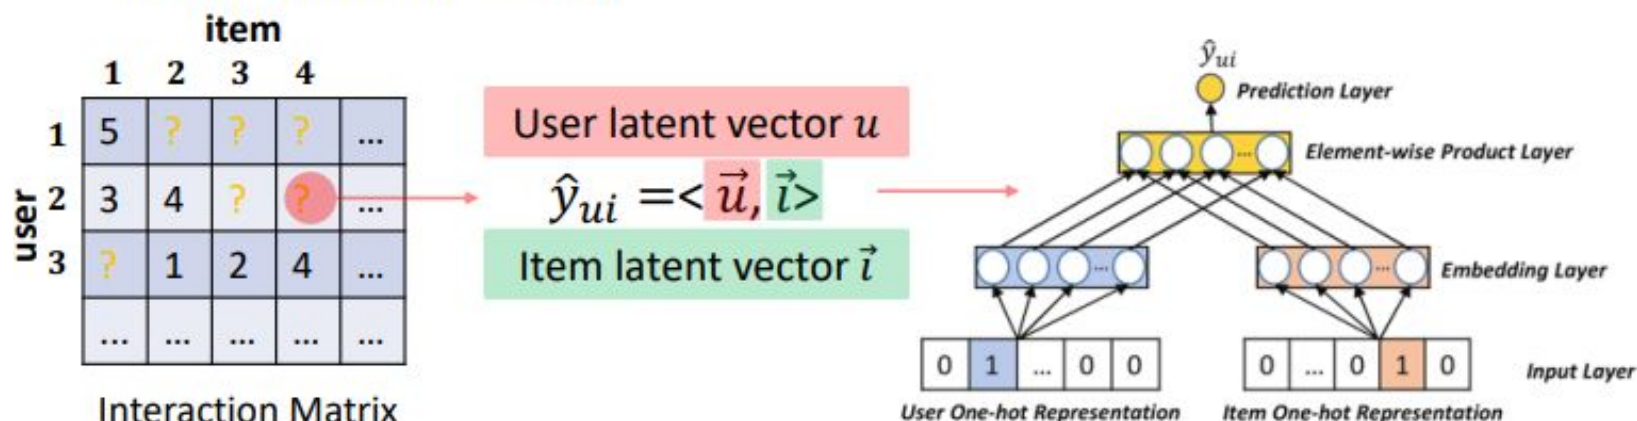

2. Model-based CF:

Predict by **inferring** from an underlying model.

Model-based CF

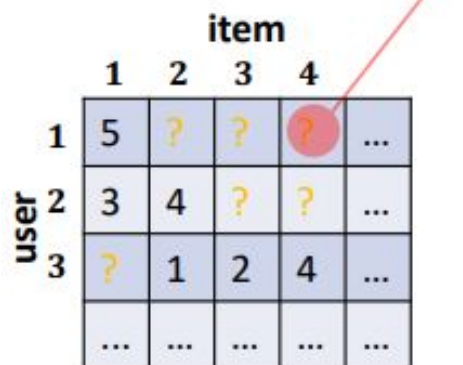

Matrix Factorization (MF) is the most popular and effective model-based CF method.

- It represents a user and an item as a vector of latent factors.
- The score is estimated as the **inner product** of user latent vector and item latent vector.

- Optimizing a loss to minimize the prediction error on training data can get the latent vectors.

Memory-based CF

		item			
		1	2	3	4
user	1	5	?	?	?
	2	3	4	?	?
	3	?	1	2	4

Interaction Matrix

Problem: predict user u 's rating on item i .

- User-based CF leverages the ratings of u 's **similar users** on the target item i .

$$\hat{y}_{ui} = \sum_{u' \in S_u(u)} \text{sim}(u, u') \cdot y_{u'i}$$

Similar users of u
Rating of a similar user on i

- Item-based CF leverages the ratings of u on other **similar items** of i .

$$\hat{y}_{ui} = \sum_{i' \in S_i(i)} \text{sim}(i, i') \cdot y_{ui'}$$

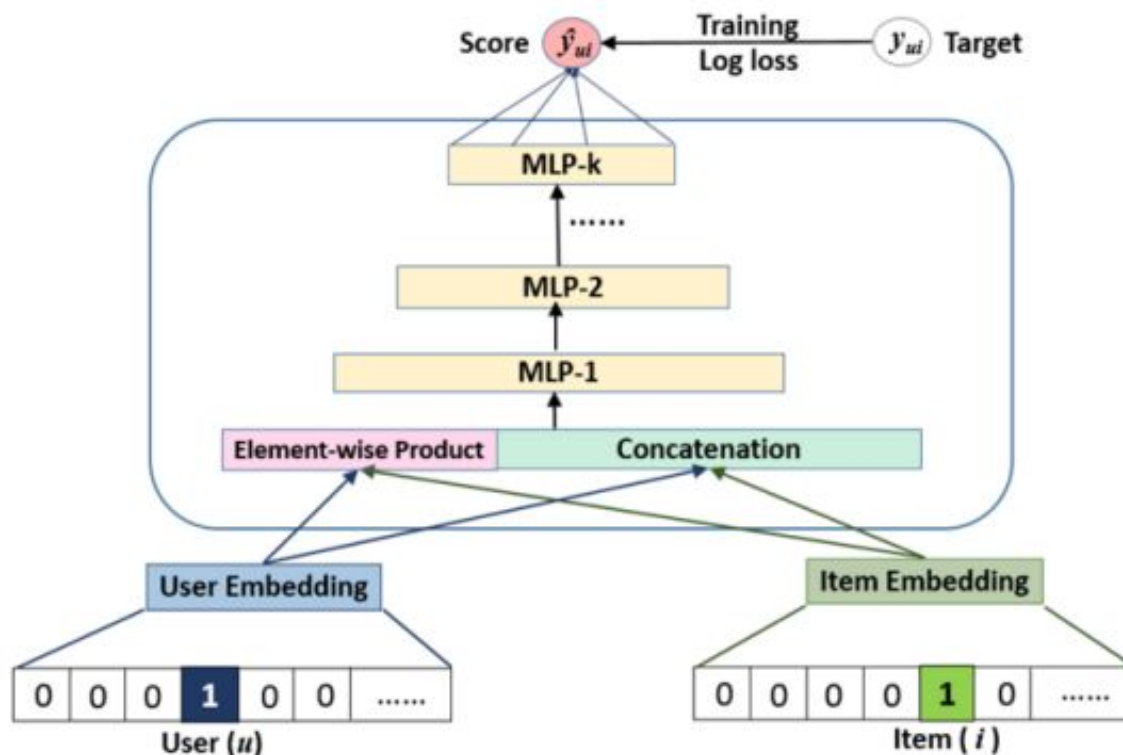

Similar items of i
Rating of u on a similar item

- Many similarity measures can be used, e.g., Jaccard, Cosine, Pearson Correlation. Recent advance learns the similarity from data.

Neural Matrix Factorization (NeuMF)

Interaction Modeling \rightarrow MF + MLP over users and items

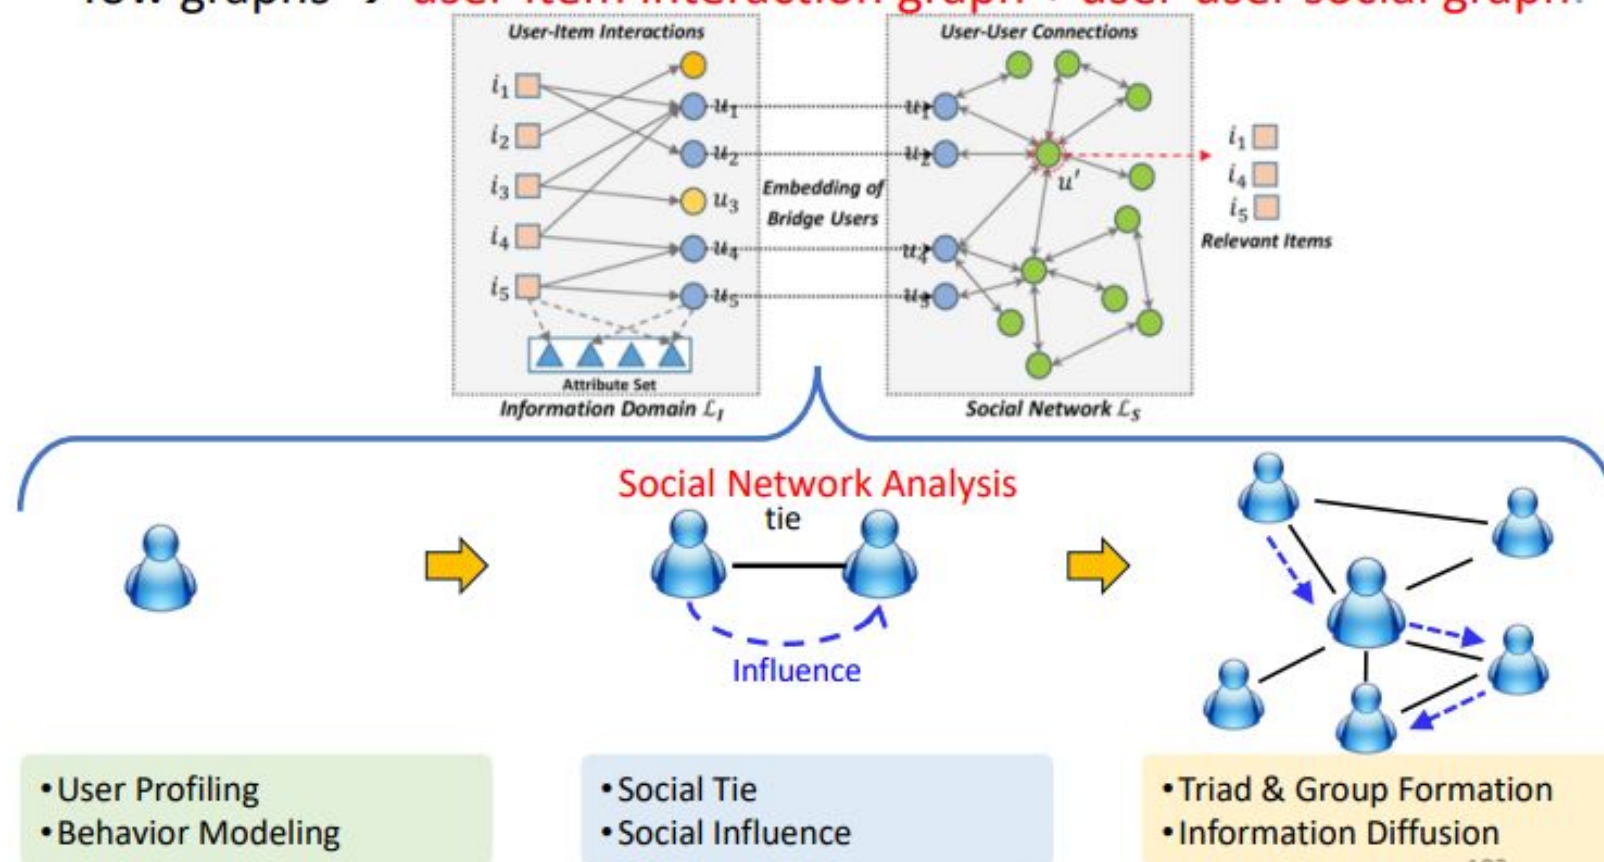

- MF uses inner product to capture the low-rank relation
- MLP is more flexible in using DNN to learn the matching function.

Social Recommendation

Social relation is of importance to help users filter information

- Two graphs \rightarrow **user-item interaction graph** + **user-user social graph**.

Graph Neural Networks for Social Recommendations (GraphRec)

GraphRec from [Fan et al, WWW'2019]

- User-Item Graph
 - Interactions between users and items
 - Users' opinions on items (i.e., explicit feedback, ratings)
- User-User Graph
 - Social relations have heterogeneous strengths
 - Strong & weak ties are mixed together
 - Users are likely to share more similar tastes with strong ties than weak ties.

User Modeling in GraphRec

These two graphs provide user information from different angles

- **Item Aggregation**

- Item space: leverage user-item interactions to get user representations

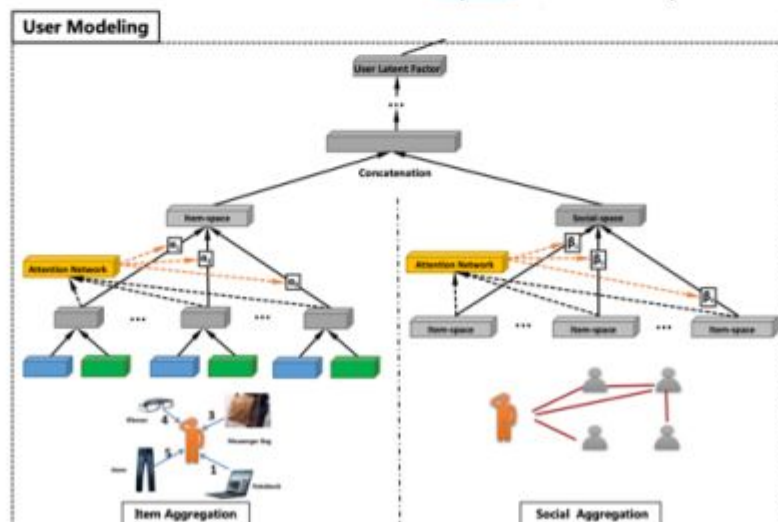

$$\mathbf{h}_i^I = \sigma(\mathbf{W} \cdot \text{Aggre}_{items}(\{\mathbf{x}_{ia}, \forall a \in C(i)\}) + \mathbf{b})$$

- **Social Aggregation**

Opinion-aware representation of an interaction

- Social space: use social relationships to get user representations

$$\mathbf{h}_i^S = \sigma(\mathbf{W} \cdot \text{Aggre}_{neighbors}(\{\mathbf{h}_o^I, \forall o \in N(i)\}) + \mathbf{b})$$

Item Modeling in GraphRec

- **User Aggregation**

- Consider both interactions & opinions to get item representations

Attention network to differentiate the importance weight

$$\mathbf{z}_j = \sigma(\mathbf{W} \cdot \text{Aggre}_{users}(\{\mathbf{f}_{jt}, \forall t \in B(j)\}) + \mathbf{b})$$

Opinion-aware representation of an interaction

- **Rating Prediction**

- Feed the concatenation of user & item representation into a neural network (MLP) to get predictions.
